Combinatorial optimization

Given a finite set E and a subset I of the power set of E (the set of feasible solutions). Given, moreover, a value (cost, length,...) $c(e)$ for all elements e of E . Find, among all sets in I , a set I such that its total value $c(I)$ (= sum of the values of all elements in I) is as small (or as large) as possible.

The parameters of a combinatorial optimization problem are: (E, I, c) .

$$\min \left\{ c(I) = \sum_{e \in I} c(e) \mid I \in I \right\}, \text{ where } I \subseteq 2^E \text{ and } E \text{ finite}$$

Important issues:

- How is I given?
- What is the encoding length of an instance?
- How do we measure running time?

Encoding and Running Times

Important issues:

- How is I given?
- What is the encoding length of an instance?
- How do we measure running time?

Special „simple“ combinatorial optimization problems

Finding a

- minimum spanning tree in a graph
- shortest path in a directed graph
- maximum matching in a graph
- a minimum capacity cut separating two given nodes of a graph or digraph
- cost-minimal flow through a network with capacities and costs on all edges
- ...

These problems are solvable in polynomial time.

Is the **number of feasible solutions** relevant?

Special „hard“ combinatorial optimization problems

CO@W

- travelling salesman problem (the prototype problem)
- location und routing
- set-packing, partitioning, -covering
- max-cut
- linear ordering
- scheduling (with a few exceptions)
- node and edge colouring
- ...

These problems are NP-hard
(in the sense of complexity theory).

Complexity Theory

co@w

- Complexity theory came formally into being in the years 1965 – 1972 with the work of Cobham (1965), Edmonds(1965), Cook (1971), Karp(1972) and many others
- Of course, there were many forerunners (Gauss has written about the number of elementary steps in a computation, von Neumann, Gödel, Turing, Post,...).
- But modern complexity theory is a the result of the combined research efforts of many, in particular, of many computer scientists and mathematical programmers trying to understand the structures underlying computational processes.

P versus NP

The Hodge Conjecture

The Poincaré Conjecture

The Riemann Hypothesis

Yang-Mills Existence and Mass Gap

Navier-Stokes Existence and Smoothness

The Birch and Swinnerton-Dyer Conjecture

Announced 16:00, on Wednesday, May 24, 2000
Collège de France

The first NP-complete Problem

Satisfiability: Is there a truth assignment to the following formula:

$$(\neg x_1 \vee x_2) \wedge (x_1 \vee x_2 \vee x_3) \wedge (x_1 \vee \neg x_2) \wedge (x_1 \vee x_2 \vee \neg x_3) \wedge (\neg x_1 \vee \neg x_2)$$

Truly important Application:

Verification of computer chips and
"systems on chips"

A design is correct iff a certain SAT formula associated with the chip has no truth assignment.

Moore's Law

1947:

The travelling salesman problem

Given n „cities“ and „distances“ between them. Find a tour (roundtrip) through all cities visiting every city exactly once such that the sum of all distances travelled is as small as possible. (TSP)

The TSP is called **symmetric** (STSP) if, for every pair of cities i and j , the distance from i to j is the same as the one from j to i , otherwise the problem is called **aysmmetric** (ATSP).

The travelling salesman problem

Two mathematical formulations of the TSP

1. *Version :*

Let $K_n = (V, E)$ be the complete graph (or digraph) with n nodes and let c_e be the length of $e \in E$. Let H be the set of all hamiltonian cycles (tours) in K_n . Find

$$\min \{c(T) \mid T \in H\}.$$

2. *Version :*

Find a cyclic permutation π of $\{1, \dots, n\}$ such that

$$\sum_{i=1}^n c_{i\pi(i)}$$

is as small as possible.

- Does that help solve the TSP?

Given a collection of cities and the cost of travel between each pair of them, the **traveling salesman problem**, or **TSP** for short, is to find the cheapest way of visiting all of the cities and returning to your starting point. In the case we study, the travel costs are symmetric in the sense that traveling from city X to city Y costs just as much as traveling from Y to X .

<http://www.tsp.gatech.edu/>

The simplicity of the statement of the problem is deceptive -- the TSP is one of the most intensely studied problems in computational mathematics and yet no effective solution method is known for the general case. Indeed, the resolution of the TSP would settle the P versus NP problem and fetch a \$1,000,000 prize from the Clay Mathematics Institute.

5. Heuristics
6. How combinatorial optimizers do it

Mathematical problems related to the traveling salesman problem were treated in the 1800s by the Irish mathematician **Sir William Rowan Hamilton** and by the British mathematician **Thomas Penyngton Kirkman**. The picture below is a photograph of Hamilton's Icosian Game that requires players to complete tours through the 20 points using only the specified connections. A nice discussion of the early work of Hamilton and Kirkman can be found in the book *Graph Theory 1736-1936* by N. L. Biggs, E. K. Lloyd, and R. J. Wilson, Clarendon Press, Oxford, 1976.

Usually quoted as
the forerunner of
the TSP →

Usually quoted as
the origin of
the TSP ↓

The general form of the TSP appears to have been first studied by mathematicians starting in the 1930s by **Karl Menger** in Vienna and Harvard. The problem was later promoted by **Hassler Whitney** and **Merrill Flood** at Princeton. A detailed treatment of the connection between Menger and Whitney, and the growth of the TSP as a topic of study can be found in **Alexander Schrijver's** paper "On the history of combinatorial optimization (till 1960)".

Der Handlungsreisende wie er sein soll

- When was this invented?

The TSP in archeology

CO@W

- Flinders Petrie (1853-1942) and the Luxor graves
- In the words of James Baikie, author of the book *A Century of Excavation in the Land of the Pharaohs*, "if the name of any one man must be associated with modern excavation as that of the chief begetter of its principles and methods, it must be the name of Professor Sir W.M. Flinders Petrie. It was he...who first called the attention of modern excavators to the importance of "unconsidered trifles" as means for the construction of the past...the broken earthenware of a people may be of far greater value than its most gigantic monuments."
- Petrie began to analyze the grave goods methodically. Grave A might contain certain types of pot in common with Grave B; Grave B also contained a later style of pot, the only type to be found in Grave C. By writing cards for each grave and **filing them in logical order**, Petrie established a full sequence for the cemetery, concluding that the last graves were probably contemporary with the First Dynasty. The development of life along the Nile thus was revealed, from early settlers to farmers to political stratification.

The TSP in archeology: Flinders Petrie's contribution

- Introduction of the "Hamming distance of graves", before Richard Wesley Hamming (1915 –1998) introduced it in mathematics.

(The Hamming distance is used in telecommunication to count the number of flipped bits in a fixed-length binary word, an estimate of error. Hamming weight analysis of bits is used in several disciplines including information theory, coding theory, and cryptography.)

- Definition of the hamiltonian path problem through "graves".

The Seminal DFJ-Paper of 1954

SOLUTION OF A LARGE-SCALE TRAVELING-SALESMAN PROBLEM*

G. DANTZIG, R. FULKERSON, AND S. JOHNSON

The Rand Corporation, Santa Monica, California

(Received August 9, 1954)

It is shown that a certain tour of 49 cities, one in each of the 48 states and Washington, D. C., has the shortest road distance.

Some Quotes from DFJ 1954

CO@W

Since there are only a finite number of possibilities (at most $\frac{1}{2}(n-1)!$) to consider, the problem is to devise a method of picking out the optimal arrangement which is reasonably efficient for fairly large values of n .

For undirected tours, the symbol x_{IJ} will be treated identically with x_{JI} so that we may rewrite (1) as

$$\sum_{j=1}^n x_{IJ} = 2. \quad (x_{IJ} \geq 0; I=1, 2, \dots, n; I \neq J; x_{IJ} \equiv x_{JI}) \quad (2)$$

IP Formulation

The problem is to find the minimum of the linear form

$$D(x) = \sum_{I>J} d_{IJ} x_{IJ}, \quad (3)$$

where the $x_{IJ}=0$ or 1 and the $x_{IJ}=1$ form a tour, and where the summation in (3) extends over all indices (I,J) such that $I>J$.

To make a linear programming problem out of this (see ref. 2) one

Polyhedral Approach

397

needs, as we have observed, a way to describe tours by more linear restraints than that given by (2). This is extremely difficult to do as illustrated by work of I. Heller⁴ and H. Kuhn.⁶ They point out that such relations always exist. However, there seems to be no simple way to characterize them and for moderate size n the number of such restraints appears to be astronomical. In spite of these difficulties, this paper will

An important class of conditions that tours satisfy, which excludes many non-tour cases satisfying (2), are the 'loop conditions.' These are linear inequality restraints that exclude subcycles or loops. Consider a non-tour solution to (2) which has a subtour of $n_1 < n$ cities; we note that the sum of the x_{IJ} for those links (I,J) in the subtour is n_1 . Hence we can

eliminate this type of solution by imposing the condition that the sum of x_{IJ} over all links (I,J) connecting cities in the subset S of n_1 cities be less than n_1 , i.e.,

$$\sum_S x_{IJ} \leq n_1 - 1 \quad (4)$$

where the summation extends over all (I,J) with I and J in the n_1 cities S . From (2) we note that two other conditions, each equivalent to (4), are

$$\sum_{\bar{S}} x_{IJ} \leq n - n_1 - 1, \quad (5)$$

where \bar{S} means the summation extends over all (I,J) such that neither I nor J is in S , and

$$\sum_{S\bar{S}} x_{IJ} \geq 2, \quad (6)$$

where $S\bar{S}$ means that the summation extends over all (I,J) such that I is in S and J not in S .

There are, however, other more complicated types of restraints which sometimes must be added to (2) in addition to an assortment of loop conditions in order to exclude solutions involving fractional weights x_{IJ} . In the 49-city case we needed two such conditions. However, later when

Subtour
Elimination
Constraints
in
several forms

Remarks

- The preprint version is much clearer than the published paper. The editors have replaced abstract insight by a sequence of examples and thus almost destroyed the “real” contents of the paper.
- The authors outline the [branch and bound technique](#).
- They explain the [cutting plane methodology](#) and observe clearly where the difficulties and chances of this method are.
- They mention the importance of [heuristics](#).
- They are modest:

CONCLUDING REMARK

It is clear that we have left unanswered practically any question one might pose of a theoretical nature concerning the traveling-salesman problem; however, we hope that the feasibility of attacking problems involving a moderate number of points has been successfully demonstrated, and that perhaps some of the ideas can be used in problems of similar nature.

*Winner of the 2007 Lanchester Prize,
INFORMS*

Princeton University Press 2006, 606 pp.

Our primary concern in this book is to describe a method and computer code that have succeeded in solving a wide range of large-scale instances of the TSP. Along the way we cover the interplay of applied mathematics and increasingly more powerful computing platforms, using the solution of the TSP as a general model in computational science.

CO@W

1. Introduction
2. The TSP and some of its history
3. The TSP and some of its variants
4. Some applications
5. Heuristics
6. How combinatorial optimizers do it

Need for Heuristics

- Many real-world instances of hard combinatorial optimization problems are (still) too large for exact algorithms.
- Or the time limit stipulated by the customer for the solution is too small.
- Therefore, we need heuristics!
- Exact algorithms usually also employ heuristics.
- What is urgently needed is a decision guide:

Which heuristic will most likely work well on what problem ?

Primal and Dual Heuristics

- **Primal Heuristic:** Finds a (hopefully) good feasible solution.
- **Dual Heuristic:** Finds a bound on the optimum solution value (e.g., by finding a feasible solution of the LP-dual of an LP-relaxation of a combinatorial optimization problem).

Minimization:

$$\text{dual heuristic value} \leq \text{optimum value} \leq \text{primal heuristic value}$$

(In maximization the inequalities are the other way around.)

quality guarantee
in practice and theory

Primal and Dual Heuristics

Primal and Dual Heuristics give rise to **worst-case guarantee**:

Minimization:

optimum value \leq primal heuristic value

$\leq (1+\varepsilon)$ optimum value

dual heuristic value \leq primal heuristic value

$\leq (1+\varepsilon)$ dual heuristic value

(In maximization the inequalities are the other way around.)

quality guarantee

-

An Unfortunate Development

- There is a marketing battle going on with unrealistic, or even ideological, claims about the quality of heuristics – just to catch attention
- Linguistic Overkill:

Voodoo Approach

A Quote

Quote:

Genetic Programming is an evolutionary computation technique which searches for those computer programs that best solve a given problem.

(Will this also solve $P = NP$?)

from the Preface

- Optimization is a procedure of finding and comparing feasible solutions until no better solution can be found.
- Evolutionary algorithms (EAs), on the other hand, can find multiple optimal solutions in one single simulation run due to their population-approach. Thus, EAs are ideal candidates for solving...

Heuristics: A Survey

Currently best heuristic with respect to worst-case guarantee:

Christofides heuristic

- compute a shortest spanning tree
- compute a minimum perfect 1-matching of the graph induced by the odd nodes of the minimum spanning tree
- the union of these edge sets is a connected Eulerian graph
- turn this graph into a TSP-tour by making short-cuts.

For distance functions satisfying the triangle inequality, the resulting tour is at most 50% above the optimum value

Understanding Heuristics, Approximation Algorithms

- **worst case analysis**
 - There is no polynomial time approx. algorithm for STSP/ATSP.
 - Christofides algorithm for the STSP with triangle inequality
- **average case analysis**

Polyhedral Theory (of the TSP)

STSP-, ATSP-, TSP-with-side-constraints-

Polytope := Convex hull of all incidence
vectors of feasible tours

$$Q_T^n := \text{conv}\{\chi^T \in \mathbf{Z}^E \mid T \text{ tour in } K_n\} \quad (\chi_{ij}^T = 1 \text{ if } ij \in T, \text{ else } = 0)$$

To be investigated:

- Dimension
- Equation system defining the affine hull
- Facets
- Separation algorithms

The symmetric travelling salesman polytope

$$Q_T^n := \text{conv}\{\chi^T \in \mathbf{Z}^E \mid T \text{ tour in } K_n\} \quad (\chi_{ij}^T = 1 \text{ if } ij \in T, \text{ else } = 0)$$

$$\subseteq \{x \in \mathbf{R}^E \mid x(\delta(i)) = 2 \quad \forall i \in V\}$$

$$x(E(W)) \leq |W| - 1 \quad \forall W \subset V \setminus \{1\}, 3 \leq |W| \leq n-3$$

$$0 \leq x_{ij} \leq 1 \quad \forall ij \in E$$

- IP formulation

$$\min c^T x$$

$$x(\delta(i)) = 2 \quad \forall i \in V$$

$$x(E(W)) \leq |W| - 1 \quad \forall W \subset V \setminus \{1\}, 3 \leq |W| \leq n-3$$

$$x_{ij} \in \{0, 1\} \quad \forall ij \in E$$

- The LP relaxation is solvable in polynomial time.

Dimension of the sym TSP polytope

Theorem. $\dim Q_T^n = \frac{1}{2}n(n-3) = |E| - |V| = \binom{n}{2} - n$

- (a) The matrix A defined by $x(\delta(i)) = 2 \ \forall i \in V$ has full row rank.
- (b) Q_T^n contains $|E| - |V| + 1$ linearly independent points.

Proof : (a) The submatrix B of A consisting of all rows and a set of columns corresponding to a spanning tree T plus an edge that forms one odd cycle with T is a nonsingular matrix.

- (b) Use Lucas' result that a complete graph with $2k+1$ nodes can be partitioned into k Hamiltonian cycles, and a complete graph with $2k$ nodes into $k-1$ Hamiltonian cycles and one perfect matching to construct the desired points (incidence vectors of tours). Show cases $n=4,5,6$ on the blackboard.

Relation between IP and LP-relaxation

Open Problem:

- If costs satisfy the triangle inequality, then

$$\text{IP-OPT} \leq \frac{4}{3} \text{ LP-SEC}$$

$$\text{IP-OPT} \leq \frac{3}{2} \text{ LP-SEC (Wolsey)}$$

Facets of the TSP polytope

- Finding facets!
- Proving that an inequality defines a facet!
- Finding exact or heuristic separation algorithms to be used in a cutting plane algorithm!

Why are facets important?

An integer programming formulation from a textbook:

$$\min c^T x$$

$$x(\delta(i)) = 2 \quad \forall i \in V$$

$$x(E) = n$$

$$x(C) \leq |C| - 1 \quad \forall C \subset E, C \text{ a nonhamiltonian cycle}$$

$$x_{ij} \in \{0, 1\} \quad \forall ij \in E$$

What would you say?

Subtour elimination constraints: equivalent versions

- SEC constraints
- cut constraints

General cutting plane theory: Gomory Cut (the „rounding trick“)

Let $P = \{x \in \mathbf{R}^n \mid Ax \leq b\}$ be a polyhedron, and we suppose that A and b are integral.

We would like to describe the convex hull P_I of all integral points in P .

Observation: For any $y \in \mathbf{R}^m$

$$y^T Ax \leq y^T b$$

is a valid inequality for P .

Observation: For any $y \in \mathbf{R}^m$

$$\lfloor y^T Ax \rfloor \leq \lfloor y^T b \rfloor$$

is a valid inequality for P_I .

$$\lfloor y^T Ax \rfloor = \sum_{j=1}^n \sum_{i=1}^m \lfloor y_i a_{ij} \rfloor x_j \leq \left\lfloor \sum_{i=1}^m y_i b_j \right\rfloor$$

Choose y so that $y_i a_{ij}$ is integral:

$$\lfloor y^T Ax \rfloor = \sum_{j=1}^n \sum_{i=1}^m y_i a_{ij} x_j \leq \left\lfloor \sum_{i=1}^m y_i b_j \right\rfloor$$

Chvátal-Gomory Procedure

- Does the rounding procedure deliver P_I ?
- How many rounds of rounding do we need?
- Other better methods?

General cutting plane theory: Gomory Mixed-Integer Cut

- Given $y, x_j \in \mathcal{C}_+$, and

$$y + \sum a_{ij} x_j = d = \lfloor d \rfloor + f, \quad f > 0$$

- Rounding:** Where $a_{ij} = \lfloor a_{ij} \rfloor + f_j$, define

$$t = y + \sum (\lfloor a_{ij} \rfloor x_j : f_j \leq f) + \sum (\lceil a_{ij} \rceil x_j : f_j > f) \in \mathcal{C}$$

- Then

$$\sum (f_j x_j : f_j \leq f) + \sum (f_j - 1) x_j : f_j > f = d - t$$

- Disjunction:**

$$t \leq \lfloor d \rfloor \Rightarrow \sum (f_j x_j : f_j \leq f) \geq f$$

$$t \geq \lceil d \rceil \Rightarrow \sum ((1 - f_j) x_j : f_j > f) \geq 1 - f$$

- Combining

$$\sum ((f_j / f) x_j : f_j \leq f) + \sum (\lceil (1 - f_j) / (1 - f) \rceil x_j : f_j > f) \geq 1$$

From SECs to

- 2-matching constraints
- combs
- clique tree inequalities
- etc.

Clique Tree Inequalities

CO@W

Clique Tree Inequalities

$$\sum_{i=1}^h x(\partial(H_i)) + \sum_{j=1}^t x(\partial(T_j)) \geq \sum_{i=1}^h |H_i| + h + 2t$$

$$\sum_{i=1}^h x(E(H_i)) + \sum_{j=1}^t x(E(T_j)) \leq \sum_{i=1}^h |H_i| + \sum_{i=1}^t (|T_j| - t_j) - \frac{t+1}{2}$$

Valid Inequalities for STSP

- Trivial inequalities
- Degree constraints
- Subtour elimination constraints
- 2-matching constraints, comb inequalities
- Clique tree inequalities (comb)
- Bipartition inequalities (clique tree)
- Path inequalities (comb)
- Star inequalities (path)
- Binested Inequalities (star, clique tree)
- Ladder inequalities (2 handles, even # of teeth)
- Domino inequalities
- Hypohamiltonian, hypotraceable inequalities
- etc.

A very special case

Petersen graph, $G = (V, F)$,
the smallest hypohamiltonian graph

$x(F) \leq 9$ defines a facet of Q_T^{10}

but not a facet of $Q_T^n, n \geq 11$

9	20,160	42,104,442	192
10	181,440	$\geq 52,043.900.866$	$\geq 15,379$

Separation Algorithms

CO@W

- Given a system of valid inequalities (possibly of exponential size).
- Is there a polynomial time algorithm (or a good heuristic) that,
 - given a point,
 - checks whether the point satisfies all inequalities of the system, and
 - if not, finds an inequality violated by the given point?

Separation

CO@W

Grötschel, Lovász, Schrijver:
Separation and optimization
are polynomial time equivalent.

Separation Algorithms

CO@W

- There has been great success in finding exact polynomial time separation algorithms, e.g.,
 - for subtour-elimination constraints
 - for 2-matching constraints (Padberg&Rao, 1982)
- or fast heuristic separation algorithms, e.g.,
 - for comb constraints
 - for clique tree inequalities
- and these algorithms are practically efficient

Polyhedral Combinatorics

This line of research has resulted in powerful cutting plane algorithms for combinatorial optimization problems.

They are used in practice to solve exactly or approximately (including branch & bound) large-scale real-world instances.

How do we solve a TSP like this?

- **Upper bound:**

Heuristic search

- Chained Lin-Kernighan

- **Lower bound:**

- Linear programming
- Divide-and-conquer
- Polyhedral combinatorics
- Parallel computation
- Algorithms & data structures

The **LOWER BOUND** is the mathematically and algorithmically hard part of the work

Work on LP relaxations of the symmetric travelling salesman polytope

$$Q_T^n := \text{conv}\{\chi^T \in \mathbf{Z}^E \mid T \text{ tour in } K_n\}$$

$$\min c^T x$$

$$x(\delta(i)) = 2 \quad \forall i \in V$$

$$x(E(W)) \leq |W| - 1 \quad \forall W \subset V \setminus \{1\}, 3 \leq |W| \leq n - 3$$

$$0 \leq x_{ij} \leq 1 \quad \forall ij \in E$$

~~$$x_{ij} \in \{0, 1\} \quad \forall ij \in E$$~~

- almost 15 years of code development
- have made their code CONCORDE available in the Internet

Concorde TSP Solver

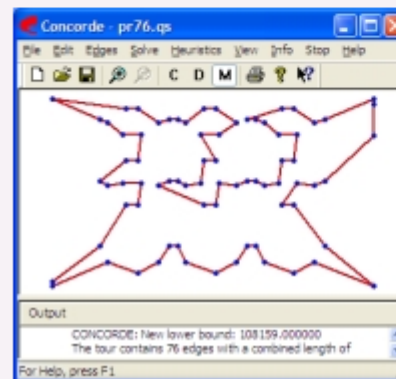

Concorde is a computer code for the symmetric traveling salesman problem (TSP) and some related network optimization problems. The code is written in the ANSI C programming language and it is available for academic research use; for other uses, contact [William Cook](#) for licensing options.

Concorde's TSP solver has been used to obtain the optimal solutions to 107 of the 110 [TSPLIB](#) instances; the largest having [15,112 cities](#).

The Concorde callable library includes over 700 functions permitting users to create specialized codes for TSP-like problems. All Concorde functions are thread-safe for programming in shared-memory parallel environments; the main TSP solver includes code for running over networks of UNIX workstations.

Concorde now supports the [QSOPT](#) linear programming solver. Executable versions of concorde with qsopt for Linux and Solaris are now available

[Hans Mittelmann](#) has created a [NEOS Server for Concorde](#), allowing users to solve TSP instances online.
